# 要約

オーストラリア南西岸において実施したミナミマグロ1歳魚の科学加入量調査の曳縄漁獲デー タから、1996年から現在までの20年以上に及ぶ加入量指数を求めた。本文書では、2023年調査 データを追加して計算した結果を、他の加入指標と比較して示す。ピストンライン曳縄指数(TRP) は、既定の調査定線(ピストンライン)上における探索距離100km当たりの漁獲をモデルベース の標準化はせずに求める。グリッドタイプ曳縄指数(TRG)は、より広範な海域のデータを使用 してデルタログノーマルアプローチで一般化線形モデルで標準化して計算した。2023年のTRG は過去2年間よりも増加したが、26年間の平均値の63%であった。TRGを他の指数と(2023年 OMMP 会合でのリファレンスセットによる OM の加入量推定値、日本はえ縄船全船による年齢 特異的標準化 CPUE の4歳魚と5歳魚のもの、航空目視指数、及び遺伝子標識の資源豊度推定 値)と比較した。2015年級までは類似したトレンドが見られていたものの、2016年級以降は差 が大きくなり、TRG は他よりも低かった。今後も、最近年の加入状況を科学調査と漁業から得ら れる全ての情報を駆使して注意深くモニタリングする必要がある。

# Summary

From the trolling catch data of the scientific recruitment monitoring surveys for the age-1 southern bluefin tuna (SBT) *Thunnus maccoyii* on the southwestern coast of Australia, the recruitment index for more than 20 years since 1996 to the present was calculated. This document shows updated indices by adding the 2023 survey data, as well as comparison to

various other recruitment indices. The piston-line trolling index (TRP) is derived from catch per 100 km search distance on a pre-determined transect line (called piston-line) without model-based standardization. The grid-type trolling index (TRG) was calculated based on data from wider area and standardized by the generalized linier model with delta lognormal approach. TRG in 2023 was higher than in the previous two years, but 63% of the 26-year average. TRG was compared to various other indices: the recruitment estimated from the OMMP meeting in 2023 based on the reference set operating model, age specific standardized CPUE from all Japanese longline vessels for age-4 and age-5, the aerial survey index, and the abundance estimates of gene tagging. Although similar trends were seen up to the 2015 year class, the difference was large after the 2016 year class that TRG is lower than others. It is necessary to continue to carefully monitor the status of recruitment in recent years by making full use of various information from scientific researches as well as from fisheries.

CCSBT-ESC/2308/21

# Introduction

Trolling survey for southern bluefin tuna (*Thunnus maccoyii* SBT) is a scientific research survey which aims to provide recruitment indices of the stock at age-1. The survey has been carried out in the southern coast of Western Australia since 2006, except 2015. It has provided an index named the piston-line trolling index (TRP) which have been reported to CCSBT since 2006 (Itoh and Kurota 2006, Itoh 2007, Itoh and Sakai 2007, 2008, 2009, 2010, Itoh et al. 2011, 2012, 2013, Itoh and Tokuda 2014, Itoh and Tsuda 2016, Tsuda and Itoh 2017, 2018, 2019, Itoh and Tsuda 2020, Itoh 2021, 2022). TRP is derived from catch per 100 km search distance on a pre-determined transect line (called piston-line) without model-based standardization. In addition, another recruitment index, the grid-type trolling index (TRG) which used data from wider area and standardized by the generalized linier model (GLM) has developed and has been reported to CCSBT since 2014 (Itoh and Takahashi 2014).

In 2021, while the trolling survey was conducted, the survey area was limited to off Esperance only due to the influence of COVID-19, which resulted in no surveys on the pistonline. We presented the updated TRG and provided a variation of TRG (TRG\_esp) limited to the area off Esperance. In 2022, the trolling survey was carried out in full range scale including piston-line, though still under the influence of COVID-19 in some extent. In 2023, the trolling survey was able to be carried out in the same specification as before 2020. In this document, we provide updated TRP and TRG, as well as comparison to various other recruitment indices.

## Materials and methods

#### 1. Piston-line Trolling Index TRP

For TRP, data used were the trolling catch data on the piston-line in the acoustic survey in 2005 and 2006 and that in the trolling survey between 2006 and 2014, 2016 to 2020, 2022 and 2023. Details of the survey were described in other papers that submitted every year (e.g. Itoh 2023). It contains data in a total of 224 times on the piston-line (Table 1). Data of another 12 times were not included because the line was incomplete due to mainly rough sea conditions. Datasets were separated between the acoustic survey and trolling survey because there were differences in the two surveys, such as survey design, a vessel used especially in size and specification of trolling gears. Trolling operations on the piston-line were repeated from 8 to 20 times per year.

The piston-line was set off Bremer Bay, in the middle of the whole area for the acoustic and trolling surveys (Fig. 1). The exact locations and length of the line have been changed a few times since its first determination in 2005. The offshore part of the piston line, which had caught a small number of fish over the past years, was cut and extended towards the coast in

3

which available to enter for the small vessels used in the trolling survey in 2007. The data in 2005 and 2006 where locate offshore than the 2007 end points were eliminated (no SBT were caught in the eliminated data). The locations of the piston-line have been almost the same since 2008 to the present. Figure 2 shows the piston-line in 2023. The vessel proceeded almost without deviation on the piston line for all of 12 lines.

The summary of data is shown in Table 2. It reached a total of 582 hours in search time and 7,489 km in search distance. The number of age-1 SBT caught was 779 individuals.

TRP was calculated as a catch of age-1 SBT per 100 km search distance. There were five types of catch definition and TRPs were calculated for each of them.

(1) School of age-1 SBT. A catch of age-1 SBT that apart from 2 km in distance from last catch of age-1 SBT is defined as a different school. TRP from this definition is "TRI\_2km."

(2) School of age-1 SBT. A catch of age-1 SBT that apart from 20 minutes in time from last catch of age-1 SBT is defined as a different school. TRP from this definition is "TRI\_20min."

(3) School of age-1 SBT. A catch of age-1 SBT that apart from 30 minutes in time from last catch of age-1 SBT is defined as a different school. TRP from this definition is "TRI\_30min."

(4) Number of times age-1 SBT caught. All the catches even it was likely to be from the same school were counted as different. TRP from this definition is "TRI\_Times.

(5) Number of age-1 SBT individuals. TRP from this definition is "TRI\_ind."

Confidence intervals of TRP were calculated from data sampled 1000 times by bootstrap method, and the results were shown by median, 5% and 95% points.

#### 2. Grid-type Trolling Index TRG

For TRG, data used were the trolling catch in the acoustic survey between 1996 and 2003, 2005 and 2006, and in the trolling survey between 2006 and 2014, and from 2016 and 2023. While the surveys were carried out from December in some years, the year was referred to that include January in the survey (e.g. the survey extended from December 2008 to January 2009 was referred to be the 2009 survey) in this analysis.

Search distance of trolling, catch of age-1 SBT and CPUE (catch/100km searched) were aggregated by survey type (acoustic survey / trolling survey), year, month, day, hour, longitude (0.1 degree), latitude (0.1 degree) and four area types (described later). Data west of 117.5E were eliminated.

Time intervals of a recording of latitude and longitude during the surveys differed by year.

Up to the 2005 acoustic survey, latitude and longitude were only recorded when any events occurred, including hourly environmental observation, catch, detection of anything in sonar, the arrival of transect reflection point, CTD observation, etc. Then, locations at every one minute were calculated by interpolating two points of records available. Since the 2006 surveys, locations were recorded in a short interval such as 10 or 15 seconds by GPS logger devises and mean locations by one minute were used for analysis.

In the acoustic survey, it was planned that trolling was operated in the daytime from 6 AM to 6 PM. Actual times of start and end of trolling were not recorded. Some records of catch before 6 AM and after 6 PM were eliminated. In the trolling survey, all the times of start and end of trolling operations were recorded.

Catch was limited for age-1 SBT (estimated from fork length of 40-63 cmFL) in the analysis. Catch was defined as a fish school and schools were defined as that successive catches more than 30 minutes apart were from different schools. Other definition of a school (e.g. 20 minutes apart, 2 km apart) can be possible, however, it has already confirmed that it caused little difference in the previous analysis.

In the research area, SBT distribution was distinctly different by area type which categorized as follows (Fig. 1).

- lump: Small seamounts or small islands. Its center position was measured on nautical charts.
- shelfedge: A range near 200 m isobath. The range was determined from observing SBT catch records that 3.0 km toward inshore and 0.5 km toward offshore.
- onshelf: the northern area of the shelfedge.

offshore: the southern area of the shelfedge.

The area for each grid was classified as follows. When a part of the shelfedge zone is included in the grid, it is classified as shelfedge, the coastal side is classified as onshelf, and the offshore side is classified as offshore. After that, those whose center position of any lump is included in the grid are classified as lump. Furthermore, in the case of four lumps (Figure of eight Island, Investigator Island, etc.) where the lump is large or the center of the lump is near the edge of the grid, the adjacent grid that is likely to be affected by the lump is also classified as lump. In the 2021 analysis, the number of lumps to be referred to was increased (170), so the data classification was different from the previous data.

Delta log-normal GLM was applied for CPUE standardization because of a high percentage of zero catch observations (Lo et al. 1992, Li and Jiao 2013). The delta model handles zero catch data and positive catch data in two separate sub-models, i.e. one sub-model to estimate

5

the probability of catching SBT age-1 with an assumption of binomial distribution and logit link function (binomial sub-model), and the other to fit the positive catch data with an assumption of lognormal distribution (CPUE sub-model).

Binomial sub-model:

 $\log(p/(1-p)) \sim \text{year} + \text{month} + \text{hour} + \text{area} + \text{survey} + \text{offset}(\log(\text{distance})) + \text{error}$ 

error ~ binomial

CPUE sub-model:

 $log(catch) \sim year + month + hour + area + survey + offset(log(distance)) + error$ 

error ~ gaussian

where p is the probability of positive catch, survey is either acoustic or trolling surveys, explanatory variables of year, month, hour, area and survey are treated as factors.

In this GLM standardization, the explanatory variables for the optimum model were selected based on the AIC using MuMIn package in R software v4.1.2 (R-core team 2012). The MuMIn package calculates the AIC for models of all combinations of the explanatory variables. The lowest AIC model containing the year explanatory variable was selected as the best model. Product of estimates from these two sub-models gives the final estimate of the TRG. Furthermore, the bootstrap method was applied to obtain a range of the estimate. 1000 datasets were made through stratified sampling by year.

Because the survey area in 2021 was limited to the offshore of Esperance due to the survey design temporarily revised in response to the situation of COVID-19, another TRG that limited to the off Esperance (TRG\_esp) was calculated. Eliminated data before 2012 when there is little data for this calculation, the area east of longitude 121.4E was used. There are two types of areas, onshelf and lump. As with TRG, we used a delta model consisting of a binomial submodel and a CPUE sub-model. The model structure used was similar except for the survey.

Binomial sub-model for TRG\_esp:

 $\log(p/(1-p)) \sim \text{year} + \text{month} + \text{hour} + \text{area} + \text{offset}(\log(\text{distance})) + \text{error}$ 

 $\operatorname{error} \sim \operatorname{binomial}$ 

where p is the probability of positive catch.

CPUE sub-model for TRG\_esp:

 $log(catch) \sim year + month + hour + area + offset(log(distance)) + error$ 

CCSBT-ESC/2308/21

#### error ~ gaussian

TRG is compared to TRG\_esp. TRG was also compared to various indices: the recruitment estimated from the OMMP meeting in 2023 based on the reference set operating model (OM), age specific GLM standardized CPUE from all Japanese longline vessels for age-4 and age-5, the aerial survey index, and the abundance estimates of gene tagging.

# Results

#### 1. Piston-line Trolling Index: TRP

Summary of data on piston-line is shown in Table 2. Figure 3 and Table 3 show the five types of estimated TRP by different school/catch definition. Figure 4 shows the median of the five types of indices that adjusted to the mean of each. The small differences were observed among the five type indices except 2013 where there was a large difference between school indices (TRI\_20min, 30min and 2km) and catch indices (TRI\_times and ind.). The relative index of TRI\_30min was consistent with the index from the acoustic survey in 2006. The fluctuation in TRI\_30min overtime was smaller among the five types of indices. Therefore, the TRI\_30min index which was submitted to CCSBT data exchange is used as TRP. Only one individual SBT of age-1 was caught in 12 piston lines in 2023. The TRP in 2023 was lower than in 2022, and was the lowest after 2018 and 2019 when it was zero.

#### 1. Grid-type Trolling Index: TRG

Summary of data aggregated by grid is shown in Table 4. It consists of 10,980 records in total that reach about 60,080 km search distance and 1,118 age-1 schools. One record with anomalously high CPUE (>2000) with a short distance was removed for analysis. Quite a large part of data was zero catch (90.9%).

Distributions of effort, catch and CPUE in 2023 are shown in Fig. 5. Those in previous years are available in previous document (e.g. Itoh 2022). It covers the area from Esperance to Albany through Bremer Bay as usual years. Probability of catch is different by the area type distinctively, the largest in lump (17%), followed by onshelf and shelfedge, and lowest in offshore (2.8%) (Table 5). In the positive catch, there is small difference in CPUE by area type.

Nominal CPUE is shown in Fig. 6. Note that a substantial part of the effort was made up offshore where few SBT caught from 1996 to 2005 in which to be expected to underestimate compared to the latter half period. In 2023, the nominal CPUE increased from 2022 and within the range in the past six years.

7

The selected GLM models for TRG based on the AIC were follows (Table 6):

Binomial sub-model:

 $\log(p/(1-p)) \sim \text{year} + \text{month} + \text{area} + \text{offset}(\log(\text{distance})) + \text{error}$ 

CPUE sub-model:

 $log(catch) \sim year + area + survey + offset(log(distance)) + error$ 

Relationships between the probability of catch and various variables and between CPUE and various variables in terms of least square mean are shown in Fig.7 and Fig. 8, respectively. The estimated values of each variable are shown in Table 7 and Table 8. QQ plot of CPUE submodel is shown in Fig. 9, which shows good fit in the middle part though lack of fits in both ends. LS-means of year trend in each sub-model are shown in Table 9 and Table 10. Indices of both sub-models and point estimation of TRG are shown in Table 11 and Fig. 10.

Table 12 and Figure 11 show TRG with confidence interval calculated through 1000 times bootstrap. TRG showed considerable low levels in 2000-2002, then increase in 2005-2008 and relatively high level in 2006-2016 with fluctuation from year to year. TRG values in recent years (2017-2023) have returned to relatively low levels, similar to those in 2000-2002. TRG value for 2023 is slightly larger than that in 2022, while the median is 63 % of the mean over 26 years.

#### 2. Comparison to other indices

We compared TRG with other recruitmen indices. In the comparison, the year of birth was arranged in cohort and expressed in year class (YC).

#### TRG esp

Trolling index from grid data limited to off Esperance (TRG\_esp) was calculated between 2013 and 2023 (Fig. 12). From the full models, following models were selected by AIC.

Binomial sub-model:

 $\log(p/(1-p)) \sim \text{year} + \text{offset}(\log(\text{distance})) + \text{error}$ 

CPUE sub-model:

 $log(catch) \sim year + offset(log(distance)) + error$ 

The TRG\_esp in 2023 was the second highest among TRG\_esp in ten years. Figure 13 shows comparison between TRG and TRG\_esp. Two indices are significantly correlated (Pearson's correlation coefficient, r=0.720, p < 0.05) and general trends are similar to each other, while the increase in 2023 was distinct in TRG\_esp. It is suggested that the index derived from the

survey area, reduced temporarily in 2021 only off Esperance, represents that from all survey areas.

# TRP

Figure 14 shows comparison between TRG and TRP. Two indices are significantly correlated to each other (Pearson's correlation coefficient, r=0.925, p < 0.001).

#### OM recruitment

Figure 15 shows comparison between recruitment estimated from the OMMP meeting in 2023 based on the reference set operating model (OM) and TRG by year class. The recruitment from OM has a large uncertainty in years of future projection or years based on few observed data in most recent years. The general trend of TRG is similar to that of OM recruitment between 1995YC and 2016YC, which is significantly correlated (r=0.56, p<0.05). TRG captured the historical low levels of OM recruitment in 2000-2002YC and TRG has been relatively high levels after 2005YC as same as in OM's. TRG captured increase/decrease change in OM recruitment well (e.g. 2004-2005YC and 2008-2011YC), while failed in a few years (e.g. 1998YC, 2007YC). TRG in the most recent 7 years (2016-2022YC) has been much lower than those average in 2010-2015YC. The recruitment of OM was low in 2016YC which agreed to TRG decrease. However, the recruitment of OM in 2017-2022YC were estimated to be as high as the 2010-2015YC, which is inconsistent with TRG. The 2018YC of OM which increased sharply from 2017, is the highest in the series. Two indices are not significantly correlated as a whole period (r=0.159, p > 0.05).

#### Age-4 and age-5 all vessel CPUE of Japanese longline

Figure 16 and Figure 17 show comparisons between age specific GLM standardized CPUE from all Japanese longline vessels for age-4 and age-5, respectably, and TRG. The general trends of TRG are similar to those CPUE indices up to 2016YC. The low level of TRG in 1999-2001YC and the high level in 2005-2015YC were supported by both CPUE idices. Large differences are observed in the most recent years, that although TRG dropped from 2015YC to 2016-2022YC, age-4 CPUE of 2018YC and age-5 CPUE of 2017YC are higher than 2015YC and reach the highest since 1995. Correlations with TRG are not significant in four series.

#### <u>Aerial survey</u>

Figure 18 shows comparison between aerial survey index and TRG. Aerial survey index is a mix of age-2, age-3 and age-4. In the figure, age-3 was assumed to assign a year class of the aerial survey index. The trends of both TRG and the aerial survey index were not similar to each other over time (r=-0.20, p>0.05). Note that the aerial survey index was not obtained around 2000YC when extremely low recruitment observed. The high value in 2013YC in the

CCSBT-ESC/2308/21

aerial survey was not supported by the TRG.

#### Gene tagging

Figure 19 shows comparison between age-2 abundance estimates from the gene tagging and TRG. Only four YC estimates from gene tagging are correspond to TRG. The trends of both TRG and the gene tagging estimates were not similar to each other over time (r=-0.353, p>0.05).

#### <u>5 main indices</u>

Figure 20 shows trends of five main indices (TRG, OM, age-4 W0.8, age-5 W0.8, gene tagging). The trend of TRG year class was similar to those of recruitment from OM and age-4 and age-5 standardized CPUEs of Japanese longline up to 2015YC. Those were medium level in the mid-1990s year classes, low level in the 2000YC-2002YC and high level in the 2005-2014YC.

The trend is different after 2016YC. TRG is as low to 2022YC. Information on recruitment from Japanese longline CPUE is available in 2018YC and 2017YC as age-4 or 5, which are quite high. In gene tagging, 2019YC is suggested to be higher than 2015YC-2017YC. Of the recruitment estimates from OM, 2018YC is significantly higher than previous several years.

# Discussion

The present paper provided updated Piston line trolling index (TRP) and Grid-type trolling index (TRG) of SBT recruitment indices. Both trolling indices are based on catch that is the number of schools. When we encountered SBT school in the survey, the numbers of fish individuals caught and catch times could have increased if we handled the trolling line well and/or the vessel moved well to catch up or attract the fish school. The numbers of fish individuals caught and catch times were decreased when a suspended fishing operation such as several trolling lines was tangled at one catch and we needed several minutes to solve the tangling. The numbers of fish individuals or catch time can be depends on such crew skills of trolling. The number of schools was selected as a catch to avoid the influence of crew skill. However, the definition of catch as a school for index means to set an assumption that the probability distribution of the size of school (the number of individuals per school) is the same every year.

TRG is a comprehensive index that includes not only on the piston-line but also all the area surveyed. TRG enabled to extend the years to as long as 26 years, by adding the trolling data in the acoustic survey from 1996 to 2003. The acoustic survey and the trolling survey were not originally designed to obtain TRG. However, because the acoustic survey was well designed to cruise randomly in the research area for sonar detection, the trolling catch operated simultaneously in the daytime is expected to be a random sampling in the area. While the survey area was concentrated on the piston-line in 2006 and 2007, the trolling survey was also operated in the larger area since 2008 intending development of TRG. When trolling was operated on a lump, we tried to operate trolling also in the area out of the lump so that collect data to evaluate the SBT distribution difference in area types.

In GLM standardization, the delta method which frequently used for data with a high percentage of zero observation was used. Area type was highly significant in the binomial submodel. It is well known the effect of sea bottom topography, such as lumps, on SBT distribution (Hobday and Campbell 2009). It should fully consider the effect of lumps and islands on SBT distribution for survey design. On the other hand, as Tsuda and Itoh (2017) showed, weather conditions have a negligible effect on the standardization of TRG.

In the comparison among the main indices (Fgi. 20), although similar trends were seen up to 2015YC, the difference was large after the 2016YC. It is noted that the OM recruitment estimation includes data on Japanese longline CPUE (though different CPUE series to be used this document) and gene tagging, which are not independent of each other. On the other hand, TRG is not used for the recruitment calculation by OM and is an independent index. It seems that recruitment level of the 2017YC and 2018YC are not low because the actual Japanese longline catch is good. These year-class abundance estimates in TRG may not have been accurate. The cause is not clear. One possibility is that the distribution and migration of age-1 SBT may have differed from those of other years. If so, it may have affected the distribution and migration of age-2 fish, and would affect estimates of GT. Status of other year classes more than 2020YC are totally unknown except from TRG. It is necessary to continue to carefully monitor the status of recruitment in recent years by making full use of various information from scientific researches as well as from fisheries.

#### Acknowledgment

We thank skippers and crew of the vessels engaged in the survey and Mr. Totterdell in MIRG for his help. We thank AFMA given us scientific research permission in the Australian coastal waters (#1005525).

SBT Catch is the number of school with the definition of 30 minutes is necessary to be a different school from last catch.

# Table 5. Summary data by area type

Area	N_records	Catch	C	PUE	
Alea	All	positive catch	% positive	Mean	SD
Lump	1,711	296	17.3%	25.6	43.8
Offshore	3,437	95	2.8%	27.7	32.1
OnShore	2,611	288	11.0%	27.2	31.9
Shelfedge	3,220	322	10.0%	24.2	24.7
Total	10,979	1,001	9.1%		

Table 6. AIC and selected models for two sub-models in TRG

	model	AIC		Model
Binomial sub-model	full		5689.3	pn~year + month + hour + area + survey + offset(log(dist))
	AIC selected		5676.2	pn~year + month + area + offset(log(dist))
CPUE sub-model	full		2150.1	catch~year + month + hour + area + survey + offset(log(dist))
	AIC selected		2128.0	catch~year + area + survey + offset(log(dist))

# Fig. 1. Map and area classified.

Red cross denotes on-shore, red solid circle denotes lump, green solid square denotes shelf-edge, and open blue triangle denotes offshore.

# Fig. 2. Locations of the piston-line off Bremer Bay in the 2023 survey.

Green cross marks are defined end points of the piston line. Red arrow denotes each of piston line and direction. Circles denote location where age-1 SBT caught. Dotted line is the 200 m isobath.

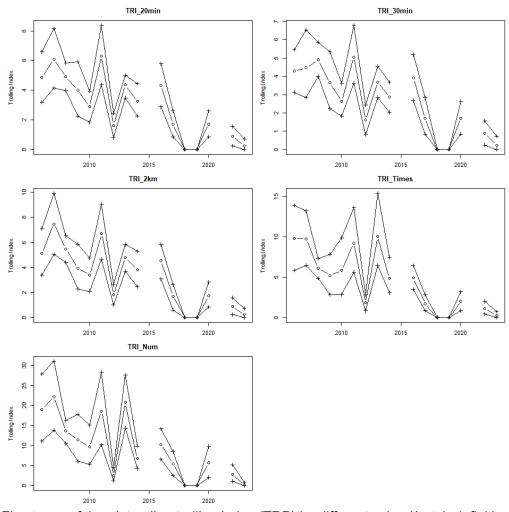

Fig. 3. Five types of the piston-line trolling index (TRP) by different school/catch definition. Showing median, 5 and 95 percentiles.

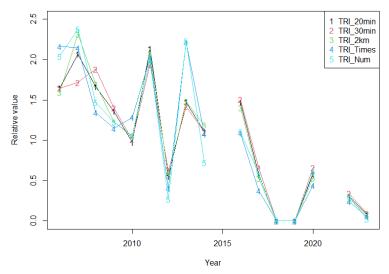

Fig. 4. Comparison of the median from five types of piston-line trolling index (TRP) by different school/catch definition.

Standardized with the mean of each index.

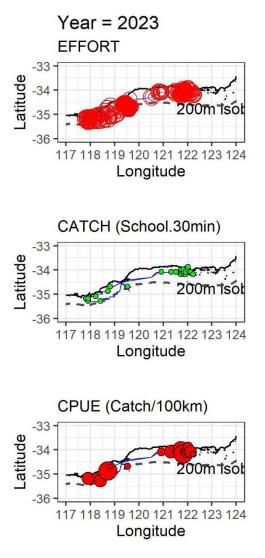

Fig. 5. Distributions of effort, age-1 SBT catch and CPUE in the 2023 survey

Blue line is the trajectory of the vessel while trolling.

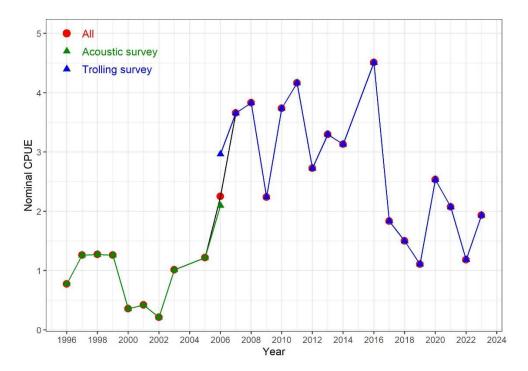

Fig. 6. Nominal CPUE of TRG.

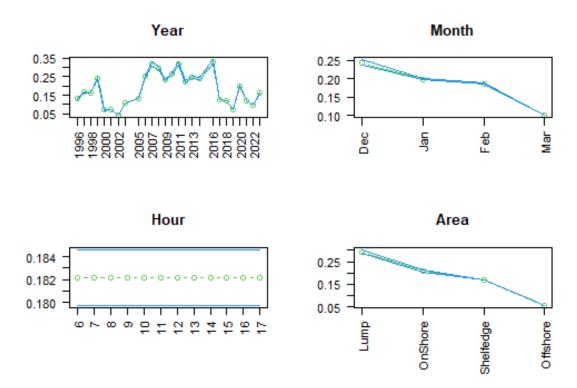

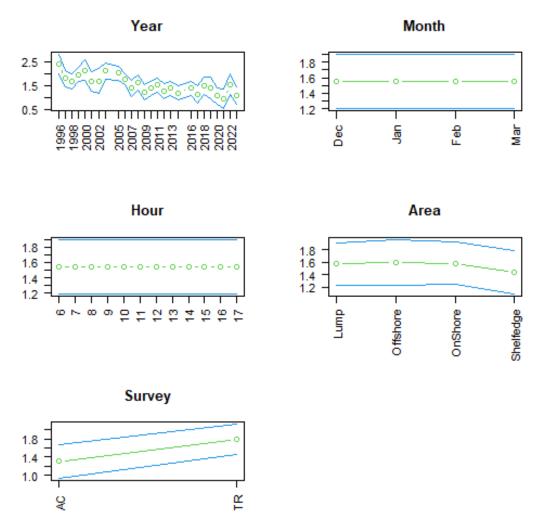

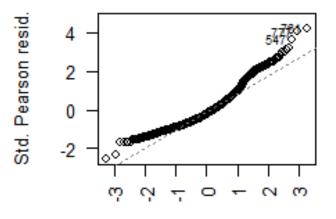

Fig. 7. Least square means of variables in binomial sub-model for TRG.
Green is mean and blue is mean±SD. Catch was defined as schools with a definition of 30 minutes is necessary for a different school. Note that hour term was not selected in the optimal model formula.

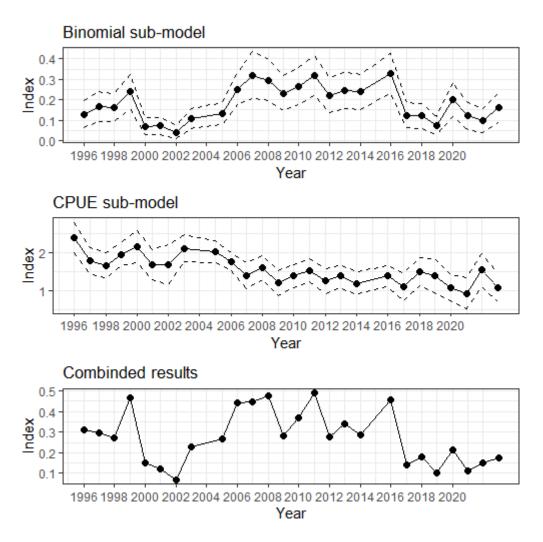

Green is mean and blue is mean  $\pm$ +SD. Catch was defined as schools with a definition of 30 minutes is necessary for a different school. Note that month and hour terms were not selected in the optimal model formula.

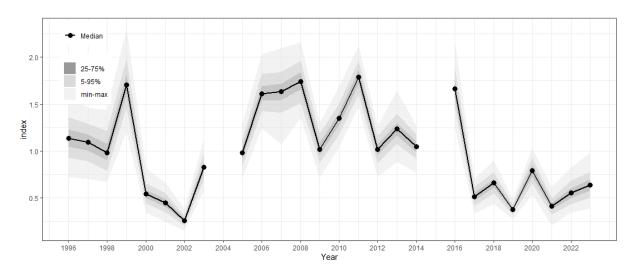

Theoretical Quantiles

Fig. 9. QQ plot of GLM for CPUE sub-model for TRG.

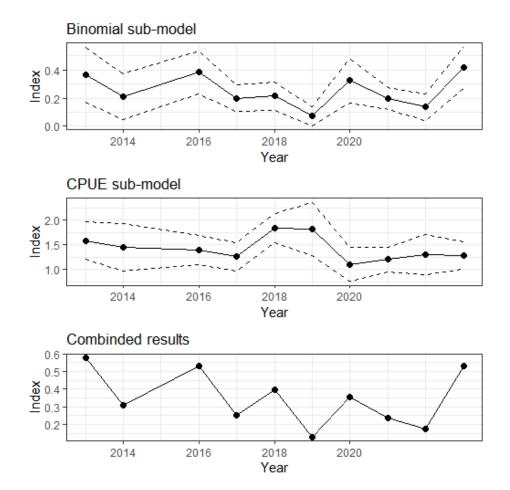

# Fig. 10. Binomial sub-model, CPUE sub-model, and combined index from two sub-models (point estimation standardized TRG).

Upper panel shows the year trend from the binomial sub-model. Mean  $\pm$  1SD. The middle panel shows the year trend form the CPUE sub-model. Mean  $\pm$  1SD. Lower panel shows TRG which is a product of two sub-models.

# Fig. 11. TRG with confidence intervals.

Estimate was simulated with 1000 times bootstrapping.

Upper panel shows the year trend from the binomial sub-model. Mean  $\pm 1$ SD. The middle panel shows the year trend form the CPUE sub-model. Mean  $\pm 1$ SD. Lower panel shows TRG\_esp which is a product of two sub-models.

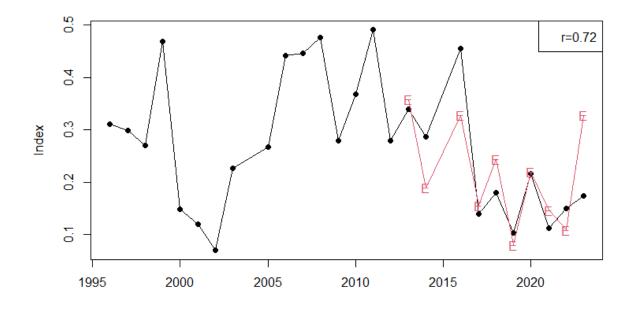

Fig. 13. Comparison between TRG and TRG\_esp where data are limited off Esperance only. Values of TRG\_esp are standardized to the mean of TRG between 2013 and 2023. Pearson's correlation *r* is 0.72 (p<0.05).

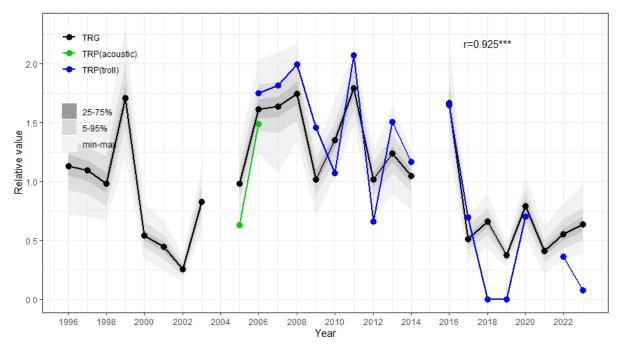

Fig. 14. Comparison between TRG and TRP. r is Pearson's correlation.

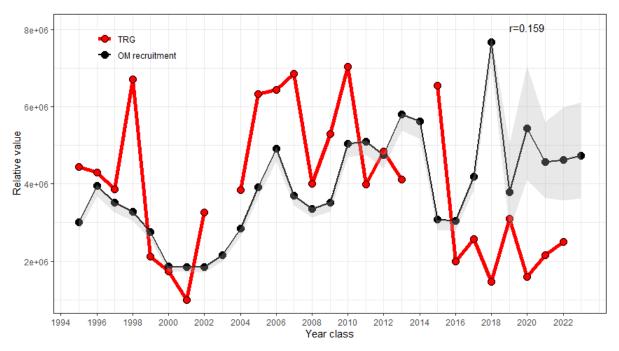

Fig. 15. Comparison between OM recruitment calculated in 2023 and TRG by year class (cohort). OM recruitment is derived from the base22.s file. Range of OM recruitment is 25-75 percentiles. Pearson's correlation *r* was calculated from data up to the 2018 year class.

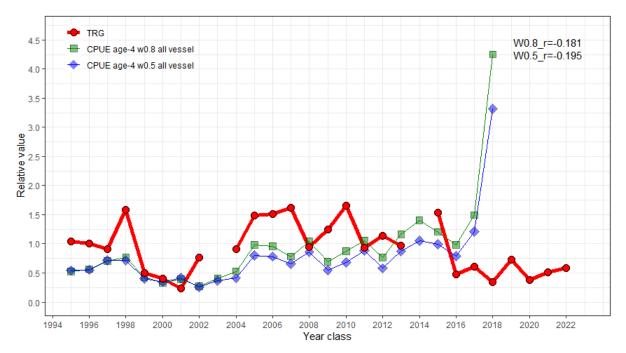

Fig. 16. Comparison between the age-4 all vessel CPUEs (w0.5 and w0.8) of Japanese longline and TRG by year class (cohort).

r is Pearson's correlation.

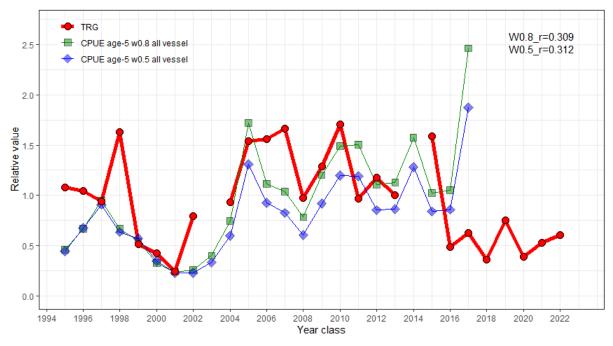

Fig. 17. Comparison between the age-5 all vessel CPUEs (w0.5 and w0.8) of Japanese longline and TRG by year class (cohort).

r is Pearson's correlation.

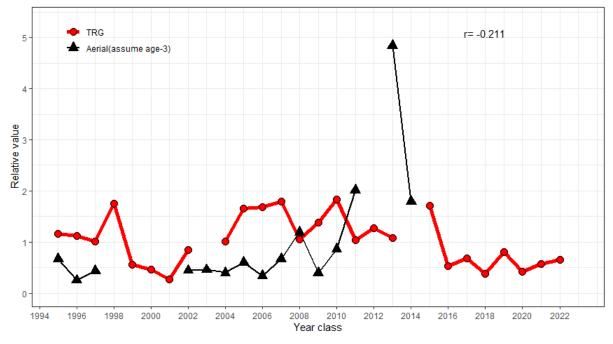

Fig. 18. Comparison between aerial survey index and TRG by year class (cohort). Assigned year class for aerial survey assuming age-3 fish observed. r is Pearson's correlation.

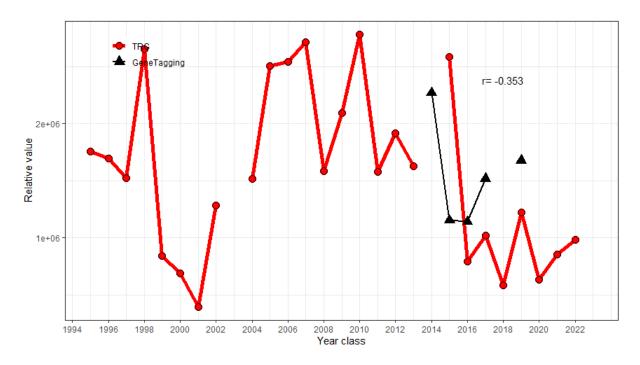

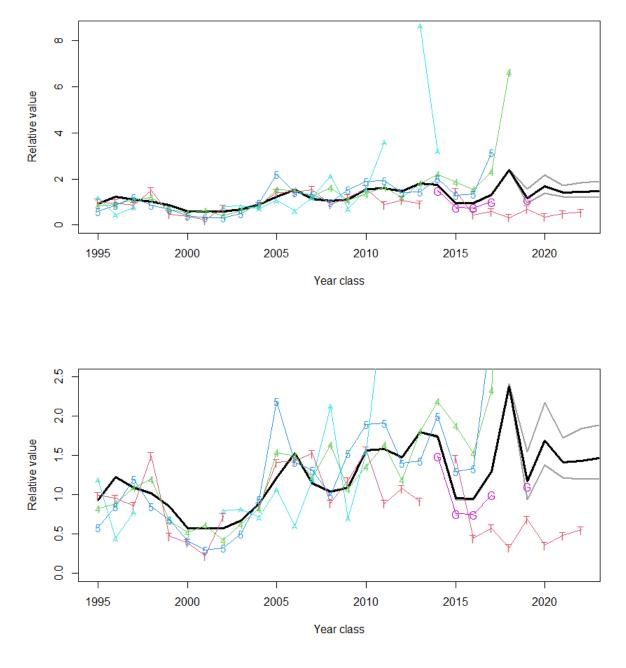

Fig. 19. Comparison between the gene tagging estimates for age-2 abundance and TRG by year class (cohort).

r is Pearson's correlation.

#### Fig. 20. Various recruitment indices by year class (cohort).

It shows the OM recruitment (thick black line. Grey lines are upper and lower values), the age-4 CPUE (w0.8) of all the Japanese longline ("4" in green), the age-5 CPUE (w0.8) of all the Japanese longline ("5" in blue), the aerial survey index ("A" in pale blue. Assuming to be age-3 fish.), gene tagging estimated value of age-2 abundance ("G" in purple), and TRG ("T" in red). Values were standardized to the mean between 1995 and 2010 year classes of each series, except the gene tagging which were to the mean between 2014 and 2019 year classes. Upper panel shows whole Y-range and lower panel shows the lower part of Y-range.
